

# Inheritance Semantics and Method Lookup

Stéphane Ducasse  
Stephane.Ducasse@univ-savoie.fr  
<http://www.iam.unibe.ch/~ducasse/>

## Goal

- Inheritance
- Method lookup
- Self/super difference

## Inheritance

- Do not want to rewrite everything!
- Often we want small changes
- We would like to reuse and extend existing behavior
- Solution: class inheritance
- Each class defines or refines the definition of its ancestors

## Inheritance

- New classes
  - Can add state and behavior:
    - color, borderColor, borderWidth, totalArea
- Can specialize ancestor behavior
  - intersect:
- Can use ancestor's behavior and state
- Can redefine ancestor's behavior
  - area to return totalArea

## Inheritance in Smalltalk

- **Single inheritance**
- **Static for the instance variables**
- At class creation time the instance variables are collected from the superclasses and the class. No repetition of instance variables.
- **Dynamic for the methods**
- Late binding (all virtual) methods are looked up at run-time depending on the dynamic type of the receiver.

## Message Sending

- **receiver selector args**
- Sending a message = looking up the method that should be executed and executing it
- **Looking up** a method: When a message (receiver selector args) is sent, the method corresponding to the message selector is looked up through the inheritance chain.

## Method Lookup

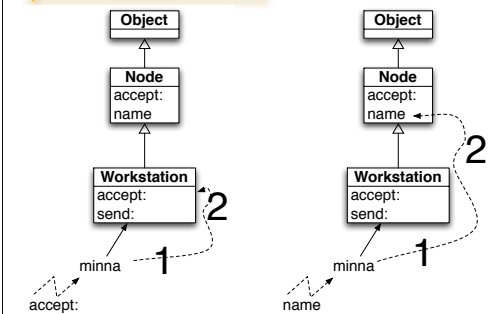

- Two steps process
- The lookup starts in the **CLASS** of the **RECEIVER**.
- If the method is defined in the method dictionary, it is returned.
- Otherwise the search continues in the superclasses of the receiver's class. If no method is found and there is no superclass to explore (class Object), this is an **ERROR**

## Lookup: class and inheritance

## Some Cases

## Method Lookup starts in Receiver Class

- aB foo
- (1) aB class => B
  - (2) Is foo defined in B?
  - (3) Foo is executed -> 50

- aB bar
- (1) aB class => B
  - (2) Is bar defined in B?
  - (3) Is bar defined in A?
  - (4) bar executed
  - (5) Self class => B
  - (6) Is foo defined in B?
  - (7) Foo is executed -> 50

S.Ducasse

## self \*\*always\*\* represents the receiver

- A new foo
- -> 10
- B new foo
- -> 10
- C new foo
- -> 50
- A new bar
- -> 10
- B new bar
- -> 10
- C new bar
- -> 50

S.Ducasse

## When message is not found

- If no method is found and there is no superclass to explore (class Object), a new method called #doesNotUnderstand: is sent to the receiver, with a representation of the initial message.

S.Ducasse

## Graphically...

S.Ducasse

## ...in Smalltalk

- node1 print: aPacket
  - node is an instance of Node
  - print: is looked up in the class Node
  - print: is not defined in Node > lookup continues in Object
  - print: is not defined in Object => lookup stops + exception
  - message: node1 doesNotUnderstand: #(aPacket) is executed
  - node1 is an instance of Node so doesNotUnderstand: is looked up in the class Node
  - doesNotUnderstand: is not defined in Node => lookup continues in Object
  - doesNotUnderstand: is defined in Object => lookup stops + method executed (open a dialog box)

S.Ducasse

## Graphically...

S.Ducasse

## Roadmap

- Inheritance
- Method lookup
- **Self/super difference**

S.Ducasse

## How to Invoke Overridden Methods?

- Solution: Send messages to super
- When a packet is not addressed to a workstation, we just want to pass the packet to the next node, i.e., we want to perform the default behavior defined by Node.

```
Workstation>>accept: aPacket
(aPacket isAddressedTo: self)
ifTrue:[Transcript show: 'Packet accepted by the Workstation ',
self name asString]
ifFalse: [super accept: aPacket]
```

- Design Hint: Do not send messages to super with different selectors than the original one. It introduces implicit dependency between methods with different names.

S.Ducasse

## The semantics of super

- Like self, **super** is a pseudo-variable that refers to the **receiver** of the message.
- It is used to invoke overridden methods.
- When using self, the lookup of the method begins in the class of the receiver.
- When using super, the lookup of the method begins in the **superclass of the class of the method containing the super expression**

S.Ducasse

## super changes lookup starting class

- A new bar
- -> 10
- B new bar
- -> 10 + 10
- C new bar
- -> 50 + 50

S.Ducasse

## super is NOT the superclass of the receiver class

Suppose the WRONG hypothesis: "The semantics of super is to start the lookup of a method in the superclass of the receiver class"

S.Ducasse

20

## super is NOT the superclass of the receiver class

mac is instance of ColoredWorkStation  
Lookup starts in ColoredWorkStation  
Not found so goes up...

accept: is defined in Workstation  
lookup stops  
method accept: is executed  
Workstation>>accept: does a super send

Our hypothesis: start in the super of the class of the receiver  
=> superclass of class of a ColoredWorkstation is ... **Workstation!**

Therefore we look in workstation **again!!!**

S.Ducasse

## What you should know

- Inheritance of instance variables is made at class definition time.
- Inheritance of behavior is dynamic.
- self **\*\*always\*\*** represents the receiver.
- Method lookup starts in the class of the receiver.
- **super** represents the **receiver** but method lookup starts in the superclass of the class **using** it.
- **Self is dynamic vs. super is static.**
